

Additional file 1: Supplementary tables

No Single Model Family Dominates: Ensembles and Conventional Machine Learning Perform Comparably to Pretrained Molecular Models Across 44 Property-Prediction Benchmarks

Scott Coffin

This file contains the eleven supplementary tables referenced in the main text. Tables S1–S7 are generated directly from the deposited benchmark artifacts by `portable_colab_qsar_bundle/render_manuscript_assets.py` and `render_latex_tables.py`; Table S8 is generated by `python -m qsarena.reliability_tables` from the reliability-study artifacts; Tables S9–S11 are generated by `qsarena.meta_analysis`, which the same render script runs. They carry the same values as the machine-readable CSV and Markdown files in the repository.

All results derive from a single split and a single seed per dataset; as set out in the Limitations section of the main text, individual entries are therefore provisional and close comparisons between models should not be treated as established.

Table S1: Per-dataset winning model under the ranking metric, with the corresponding cross-validation-selected model and its relative gap to the dataset best (%).

dataset	suite	task_ kind	family	model	analysis_ metric	analysis_ metric_value	cv_ selected_ model	cv_ selected_ family	cv_selected_gap_to_best

Table S5: Run-to-run comparison: the canonical NSF ACCESS Jetstream2 A100 benchmark against the earlier consumer-GPU (RTX 4060) run, analysed identically. "Same split" marks datasets where both runs used the identical held-out partition; the remainder were re-split to scaffold splits in the A100 run and are therefore not directly comparable. Change is relative and metric-direction aware (positive favours the A100 run).

Dataset	Task	Same split	A100 best model	A100 value	RTX 4060 best model	RTX 4060 value	Change (%)

Table S6: Dataset catalog. "Ranking metric" is the metric used for cross-dataset model ranking (RMSE for regression; the dataset's designated primary classification metric otherwise); leaderboard comparisons in Table S7 use the leaderboard's own metric, which differs for several TDC regression tasks.

Dataset	Suite	Task	Molecules	Train	Test	Split	Target scale	Ranking metric	Best model	Best value	Leaderboard metric	QSARena (lb metric)	Est. rank	Best published	Best published model

Table S7: Per-dataset leaderboard comparison, sorted by estimated rank. “References (n)” is the number of published values available for that dataset and metric; ranks from sparse reference sets are correspondingly uncertain. The **tdc_ppbr_az** top-1 reference (MAE 0.679) is inconsistent in scale with the rest of that dataset’s references (top-10 cutoff 7.914) and its top-1 gap should be disregarded.

Table S8: Applicability domain and calibration on the 22 official TDC ADMET Benchmark Group splits, for a fixed reference model (random forest, 300 trees, on Morgan radius-2 2048-bit fingerprints plus RDKit 2D descriptors) fitted to 80% of each train_val partition, with the remaining 20% used only for conformal calibration. Coverage is the fraction of test compounds inside the domain. The error ratio is the mean test error outside the domain divided by that inside it (MAE for regression, 0/1 error for classification); values above 1 mean the domain flag separates worse predictions. “Std.” is the Roy standardization approach on RDKit descriptors; “kNN” is the 5-nearest-neighbour Tanimoto distance thresholded at the 95th percentile of training distances; “Reliability” is the conformal-interval-width flag (regression) or the posterior-probability confidence flag with $|p_1 - p_0| \geq 0.5$ (classification). Conformal coverage is the empirical test coverage of 90% split-conformal intervals or prediction sets. “—” marks a ratio not reported because fewer than five test compounds fall on one side of the domain boundary. Results describe the reference model, not the benchmark’s selected model; single seed.

Table S10: Exploratory family $\times$ meta-feature associations: Spearman correlation between each meta-feature and the relative gap of the family’s best model to the per-dataset best, with a dataset-bootstrap 95% CI (10,000 resamples), a two-sided label-permutation p-value and a Benjamini–Hochberg q-value over the whole grid. Positive ρ means the family falls further behind as the meta-feature increases.

Model family	Meta-feature	Datasets	Spearman rho	95% CI	Permutation p	BH q

Table S11: Family selector (v2), leave-one-dataset-out regret: the relative gap (%) of the recommended family to the per-dataset best. Rows are pre-specified variants (model | feature blocks: F0 size, similarity, label asymmetry and task; F1 chemistry; F2 label landscape; F3 training-set CV landmarks); “sbs” always picks the family with the best record on the other datasets. The nested row chooses the variant inside an inner leave-one-dataset-out loop and is the only unbiased estimate; single variants are exploratory.

Selector (model feature blocks)	Mean regret (%)	Median regret (%)	Pick within 5% of best (%)	SBS-to-oracle gap closed
